Solution:

- The sample mean $(\bar{x})$ is an unbiased estimator of (μ) .
- Since the variance is known, the confidence interval is:

- For 95% confidence, $(z_{0.025} \approx 1.96)$.

2. Hypothesis Testing for Population Proportion

Problem: Test whether the proportion (p) in a population equals 0.6 based on a sample of size 100 with 65 successes at a 5% significance level.

Solution:

- Null hypothesis: $(H_0: p = 0.6)$
- Alternative hypothesis: $(H_1: p \neq 0.6)$
- Test statistic:

$$z = \frac{\hat{p} - p_0}{\sqrt{\frac{p_0(1 - p_0)}{n}}}$$

where $(\hat{p} = 65/100 = 0.65)$.

- Compute:

\[

$$z = \frac{0.65 - 0.6}{\sqrt{\frac{0.6 \times 0.4}{100}}} = \frac{0.05}{\sqrt{0.0024}} \approx 1.02$$

Exercise

Suppose $(X_1, X_2, \dots, X_n)$ are independent and identically distributed random variables from a normal distribution $(N(\mu, \sigma^2))$, where (σ^2) is known. Derive the maximum likelihood estimator for (μ) .

Solution Outline

- Write down the likelihood function:
- $L(\mu) = \prod_{i=1}^n \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{(X_i - \mu)^2}{2\sigma^2}\right)$.
- Take the natural logarithm to obtain the log-likelihood:
- $\ell(\mu) = -\frac{n}{2} \log(2\pi\sigma^2) - \frac{1}{2\sigma^2} \sum_{i=1}^n (X_i - \mu)^2$.
- Differentiate $\ell(\mu)$ with respect to (μ) :
- $\frac{d}{d\mu} \ell(\mu) = \frac{1}{\sigma^2} \sum_{i=1}^n (X_i - \mu)$.
- Set the derivative equal to zero and solve:

$$-\sum_{i=1}^n (X_i - \mu) = 0 \Rightarrow \hat{\mu} = \frac{1}{n} \sum_{i=1}^n X_i.$$

- Conclude that the MLE for (μ) is the sample mean.

Approach to Solving Jun Shao's Exercises

The solutions to exercises in Jun Shao's texts often involve a blend of theoretical derivation, asymptotic analysis, and probability inequalities. Here is a structured approach to tackling these problems:

Step 1: Carefully Read the Problem Statement

- Identify what is being asked: proof, derivation, computation, or conceptual explanation.
- Note the assumptions and conditions provided.

Step 2: Recall Relevant Theoretical Results

- Map the problem to known theorems or lemmas.
- For example, if the problem involves asymptotic normality, recall the CLT or Lyapunov's condition.

Step 3: Break Down the Problem into Subparts

- Simplify complex problems by dividing them into manageable parts.
- For example, to prove consistency, verify the conditions of a relevant theorem (e.g., the Law of Large Numbers).

Step 4: Engage in Step-by-Step Derivation

- Use algebraic manipulations, inequalities, and limit arguments.
- Be meticulous with assumptions about convergence (almost sure, in probability, in distribution).

Step 5: Verify Conditions and Justify Each Step

- Ensure all conditions (e.g., independence, identical distribution, boundedness) are satisfied.
- Justify the use of each theorem or inequality.

Step 6: Summarize the Result Clearly

- State the conclusion explicitly.
- Connect it back to the original question.

Illustrative Examples and Solutions

Let's explore some common exercise types inspired by Jun Shao's work, along with detailed solution strategies.

Example 1: Asymptotic Normality of the MLE

Problem: Suppose $(X_1, X_2, \dots, X_n)$ are i.i.d. random variables with a density $f(x; \theta)$, where θ is an unknown parameter. Show that under regularity conditions, the maximum likelihood estimator $\hat{\theta}_n$ is asymptotically normal:

$$\sqrt{n}(\hat{\theta}_n - \theta_0) \xrightarrow{d} N(0, I(\theta_0)^{-1}),$$

where $I(\theta_0)$ is the Fisher information.

Solution Outline:

- Step 1: Recall the regularity conditions for MLE asymptotics (differentiability, identifiability, Fisher information positivity).
- Step 2: Recognize that the MLE solves the score equation:

$$\frac{1}{n} \sum_{i=1}^n \frac{\partial}{\partial \theta} \log f(X_i; \theta) = 0.$$

\]

- Step 3: Use Taylor expansion of the score function around θ_0 :

\[

$$0 = \frac{1}{n} \sum_{i=1}^n \frac{\partial}{\partial \theta} \log f(X_i; \hat{\theta}_n) \approx \frac{1}{n} \sum_{i=1}^n \frac{\partial}{\partial \theta} \log f(X_i; \theta_0) + \left(\hat{\theta}_n - \theta_0 \right) \frac{1}{n} \sum_{i=1}^n \frac{\partial^2}{\partial \theta^2} \log f(X_i; \tilde{\theta}),$$

\]

where $\tilde{\theta}$ is between $\hat{\theta}_n$ and θ_0 .

- Step 4: Show that the score function converges in distribution to a normal distribution via the CLT, and the second derivative converges in probability to $-I(\theta_0)$.
- Step 5: Rearrange the terms to obtain the asymptotic distribution:

\[

$$\sqrt{n}(\hat{\theta}_n - \theta_0) \xrightarrow{d} N(0, I(\theta_0)^{-1}).$$

\]

Example 2: Consistency of the Sample Mean

Problem: Prove that the sample mean $\bar{X}_n = \frac{1}{n} \sum_{i=1}^n X_i$ is a consistent estimator for $\mu = E[X_i]$.

Solution Strategy:

- Step 1: Verify conditions for the Law of Large Numbers:
 - Independence (assumed).
 - Finite expectation $E[X_i]$
- Step 2: Apply the Strong Law of Large Numbers (SLLN):

\]

$\bar{X}_n \xrightarrow{\text{a.s.}} \mu.$

]

- Step 3: Alternatively, use the Weak Law of Large Numbers for convergence in probability:

[

$\bar{X}_n \xrightarrow{p} \mu.$

]

- Step 4: Conclude that $(\bar{X}_n)$ is a consistent estimator of (μ) .

Question What are the key differences between mathematical statistics and probability theory? Mathematical statistics focuses on developing methods for collecting, analyzing, and interpreting data, often involving estimation and hypothesis testing. Probability theory, on the other hand, studies the mathematical foundations of randomness and uncertainty, providing models to quantify likelihoods of events. While probability theory provides the theoretical basis, mathematical statistics applies these concepts to real-world data. **Answer** How can I approach solving a problem in mathematical statistics using a Bayesian framework? To solve a problem using Bayesian methods, start by defining a prior distribution that reflects your initial beliefs about the parameters. Then, gather data and compute the likelihood function. Using Bayes' theorem, update the prior with the likelihood to obtain the posterior distribution. Finally, analyze the posterior to make inferences or predictions about the parameters. What are common challenges faced when implementing Bayesian solutions in statistical problems? Common challenges include selecting appropriate prior distributions, especially when prior information is limited; computational complexity involved in calculating posterior distributions, especially for complex models; and ensuring convergence and mixing in Markov Chain Monte Carlo (MCMC) methods. Additionally, interpreting Bayesian results in a frequentist context can sometimes be challenging. Can you recommend resources or tools for learning Bayesian methods in mathematical statistics? Yes, popular resources include 'Bayesian Data Analysis' by Gelman et al., and online courses like Coursera's 'Bayesian Statistics' by the University of California. Software tools such as R (with packages like 'rstan' or 'brms') and Python (with libraries like PyMC3 or PyMC) are also invaluable for implementing Bayesian models and

solutions. How does the solution approach differ when using classical versus Bayesian methods in statistics? Classical (frequentist) methods rely on long-run frequency properties and often focus on point estimates, confidence intervals, and hypothesis testing without incorporating prior beliefs. Bayesian methods, however, incorporate prior information through probability distributions and produce a full posterior distribution for parameters, allowing for more flexible and probabilistic inferences. The choice depends on the problem context, available prior knowledge, and the desired interpretation of results.
