Intermediate DBMS Interview Questions and Answers

4. What is normalization? Explain its types.

Answer:

Normalization is a process of organizing data in a database to reduce redundancy and improve data integrity. It involves dividing large tables into smaller, related tables and defining relationships between them.

Types of normalization:

- First Normal Form (1NF): Ensures each column contains atomic values, and there are no repeating groups.
- Second Normal Form (2NF): Meets 1NF criteria and all non-key attributes are fully dependent on the primary key.
- Third Normal Form (3NF): Meets 2NF criteria, and all attributes are only dependent on the primary key, removing transitive dependencies.
- Boyce-Codd Normal Form (BCNF): A stronger version of 3NF, addressing certain anomalies.

5. Explain the concept of primary key and foreign key.

Answer:

- Primary Key: A unique identifier for each record in a table. It ensures each row can be uniquely identified (e.g., StudentID).
- Foreign Key: A field in one table that references the primary key of another table, establishing a relationship between the two tables.

Example:

In an `Orders` table, `OrderID` might be the primary key, while `CustomerID` in the same table could be a foreign key referencing the `CustomerID` in the `Customers` table.

6. What are indexes? Why are they used?

Answer:

Indexes are database objects that improve the speed of data retrieval operations on a table at the cost of additional writes and storage space. They function similarly to indexes in a book, allowing quick location of data.

Benefits of indexes:

- Improved performance of search operations
- Efficient sorting and filtering

Types of indexes:

- Unique Indexes
- Composite Indexes
- Bitmap Indexes

Advanced DBMS Interview Questions and Answers

7. What is transaction management? Explain ACID properties.

Answer:

Transaction management ensures that database operations are performed reliably and adhere to certain principles. A transaction is a sequence of operations performed as a single logical unit.

ACID properties:

- Atomicity: All operations in a transaction are completed or none are.
- Consistency: Ensures the database remains in a valid state before and after a transaction.
- Isolation: Transactions are executed independently without interference.
- Durability: Once committed, transaction results are permanently stored, even in case of failures.

8. Explain the concept of deadlock in DBMS.

Answer:

A deadlock occurs when two or more transactions are waiting indefinitely for resources held by each other, causing a standstill. For example, Transaction A holds Resource 1 and waits for Resource 2, while Transaction B holds Resource 2 and waits for Resource 1.

Handling deadlocks:

- Deadlock prevention strategies
- Deadlock detection and recovery
- Resource scheduling to avoid deadlock conditions

9. What is the difference between clustered and non-clustered indexes?

Answer:

- Clustered Index: Determines the physical order of data in the table. A table can have only one clustered index. Data is stored sequentially based on the index.
- Non-Clustered Index: Creates a logical order separate from the data storage. It maintains a separate structure with pointers to the data. Multiple non-clustered indexes can exist on a table.

Specialized DBMS Topics and Common Questions

10. What is Data Integrity? How is it enforced?

Answer:

Data integrity refers to the accuracy, consistency, and reliability of data stored in a database. It is enforced through constraints such as:

- Primary key constraints
- Unique constraints
- Check constraints
- Not null constraints
- Foreign key constraints

11. What is a View in SQL? What are its advantages?

Answer:

A view is a virtual table based on the result set of an SQL query. It provides a way to present data without storing it physically.

Advantages:

- Simplifies complex queries
- Enhances security by restricting access to specific data
- Provides customized data representation

Question What is a DBMS, and what are its main functions? A Database Management System (DBMS) is software that allows users to define, create, maintain, and control access to a database. Its main functions include data storage, data retrieval, data manipulation, data security, backup and recovery, and ensuring data integrity. **What are the different types of DBMS?** The primary types of DBMS are Hierarchical DBMS, Network DBMS, Relational DBMS (RDBMS), and Object-Oriented DBMS. Each type has its own data model and use cases, with RDBMS being the most widely used today. **Explain the concept of normalization and its importance.** Normalization is the process of organizing data in a database to reduce redundancy and dependency by dividing large tables into smaller, related tables. It improves data integrity, simplifies maintenance, and optimizes storage efficiency. **What is a primary key, and how does it differ from a unique key?** A primary key is a unique identifier for each record in a table and cannot contain NULL values. A unique key also enforces uniqueness but can accept NULL values (except in some DBMS). The primary key uniquely identifies records and establishes relationships between tables. **What are indexes in a database, and why are they used?** Indexes are database objects that improve the

speed of data retrieval operations by providing quick access to rows in a table based on the indexed columns. They enhance query performance but may slow down data modification operations like insert, update, and delete. Explain the difference between SQL and NoSQL databases. SQL databases are relational, structured, and use Structured Query Language (SQL) for defining and manipulating data. NoSQL databases are non-relational, often schema-less, and designed to handle large volumes of unstructured or semi-structured data, offering high scalability and flexibility. What are ACID properties in a transaction? ACID stands for Atomicity, Consistency, Isolation, and Durability. These properties ensure reliable processing of database transactions: Atomicity guarantees all-or-nothing execution; Consistency ensures data validity; Isolation prevents interference between concurrent transactions; Durability guarantees that committed transactions are permanent even in case of failures. What is a foreign key, and how does it establish relationships between tables? A foreign key is a field (or collection of fields) in one table that references the primary key in another table. It establishes a relationship between the two tables, enforcing referential integrity by ensuring that the value in the foreign key matches an existing primary key value. Describe the concept of database normalization forms. Database normalization forms are guidelines to organize database structures to reduce redundancy and dependency. The common forms include First Normal Form (1NF), Second Normal Form (2NF), Third Normal Form (3NF), and higher normal forms, each with specific rules to improve data integrity and efficiency. What are stored procedures and triggers in a DBMS? Stored procedures are precompiled SQL code that can be executed repeatedly to perform complex operations, improving performance and reusability. Triggers are special types of stored procedures automatically executed in response to certain events on a table, such as insert, update, or delete, used for enforcing rules or auditing.

Question What is OBIEE and what are its main components? **Answer** OBIEE (Oracle Business Intelligence Enterprise Edition) is a comprehensive suite of enterprise business intelligence tools. Its

main components include BI Server (logical data access layer), BI Presentation Layer (user interface), BI Scheduler (report scheduling), BI Answers (ad-hoc reporting), BI Dashboards (visual dashboards), and BI Publisher (report publishing). How does the OBIEE architecture work? OBIEE architecture involves multiple layers: Data sources (databases), the BI Server which processes requests and manages logical data modeling, the Presentation Layer for user interaction, and the Web Server that hosts the BI portal. Users create reports and dashboards that query data through the BI Server, which retrieves and processes data from underlying sources. What is a Repository (RPD) in OBIEE and how is it structured? The RPD (Repository) is a metadata repository that defines logical data models, physical data sources, and security settings. It has three main layers: Physical Layer (connects to data sources), Business Model and Mapping Layer (logical models of data), and Presentation Layer (user-visible objects). Explain the difference between a Logical Table and a Physical Table in OBIEE. A Physical Table represents the actual table in the database, while a Logical Table is an abstraction used in the Business Model layer to define how data is presented to users. Logical Tables are mapped to Physical Tables and can combine data from multiple sources. What are aggregate tables in OBIEE, and why are they used? Aggregate tables contain pre-summarized data at various levels of aggregation. They improve query performance by reducing the amount of data processed during report execution, especially for large datasets or complex calculations. How do you troubleshoot performance issues in OBIEE? Troubleshooting involves analyzing query logs, using the BI Server Diagnostics, checking for inefficient SQL queries, optimizing the RPD, creating aggregate tables, tuning the database, and reviewing report design for performance bottlenecks. What is a Prompt in OBIEE and how is it used? A Prompt is an interactive filter that allows users to select values dynamically at runtime, which then filters the data displayed in reports or dashboards. Prompts enhance report interactivity and user control over data views. Can you explain the difference between 'Session Variables' and 'Repository Variables' in OBIEE? Repository Variables are static variables defined in the RPD used for configuration or setting default values. Session Variables are dynamic variables set at runtime for individual user sessions, often used to personalize reports or control access.

Common Oracle SQL Exam Questions with Answers

Below are some frequently encountered questions in Oracle SQL certification exams, along with detailed answers and explanations. These samples are representative of the types of questions you might encounter.

Question 1: What is the purpose of the `NVL` function in Oracle SQL?

Options:

- A) To replace NULL values with a specified value
- B) To check if a value is NULL

C) To concatenate two strings

D) To convert data types

Answer: A) To replace NULL values with a specified value

Explanation: The `NVL` function in Oracle SQL is used to substitute a value when a NULL is encountered. For example:

```
```sql
```

```
SELECT employee_name, NVL(commission_pct, 0) AS commission
```

```
FROM employees;
```

```
```
```

In this query, any NULL `commission\_pct` values are replaced with 0. This function is essential for data cleaning and ensuring calculations do not result in NULLs.

Question 2: Which clause is used to filter records in Oracle SQL?

Options:

A) WHERE

B) HAVING

C) GROUP BY

D) ORDER BY

Answer: A) WHERE

Explanation: The `WHERE` clause is used to specify conditions that filter records in a SELECT statement. It retrieves only the rows that meet the specified criteria. For example:

```
```sql
```

```
SELECT FROM employees WHERE department_id = 10;
```

...

This query fetches all employees in department 10.

### Question 3: How does the `JOIN` operation work in Oracle SQL?

Options:

- A) Combines columns from multiple tables based on a related column
- B) Deletes rows from a table
- C) Creates a new table from existing tables
- D) Updates data in multiple tables simultaneously

Answer: A) Combines columns from multiple tables based on a related column

Explanation: `JOIN` allows you to retrieve data spanning multiple tables by establishing a relationship between them. The most common types are `INNER JOIN`, `LEFT JOIN`, `RIGHT JOIN`, and `FULL OUTER JOIN`. For example:

```
```sql
```

```
SELECT e.employee_id, e.employee_name, d.department_name
```

```
FROM employees e
```

```
JOIN departments d ON e.department_id = d.department_id;
```

```
```
```

This query combines data from `employees` and `departments` based on the matching `department\_id`.

### Question 4: What is the purpose of the `GROUP BY` clause?

Options:

- A) To aggregate data based on one or more columns

- B) To filter grouped data
- C) To order data in ascending or descending order
- D) To limit the number of rows returned

Answer: A) To aggregate data based on one or more columns

Explanation: The `GROUP BY` clause groups rows that have the same values in specified columns, often used with aggregate functions like `SUM`, `AVG`, `COUNT`. For example:

```
```sql  
  
SELECT department_id, COUNT() AS employee_count  
  
FROM employees  
  
GROUP BY department_id;  
  
```
```

This groups employees by department and counts them.

### Question 5: Which function is used to generate a sequence of numbers in Oracle SQL?

Options:

- A) `ROWNUM`
- B) `SEQUENCE.NEXTVAL`
- C) `RANGE`
- D) `GENERATE\_SERIES`

Answer: B) `SEQUENCE.NEXTVAL`

Explanation: In Oracle, sequences are database objects that generate unique numbers. `SEQUENCE.NEXTVAL` retrieves the next value in a sequence. For example:

```
```sql  
  
CREATE SEQUENCE emp_seq START WITH 1 INCREMENT BY 1;  
  
INSERT INTO employees (employee_id, name)  
  
VALUES (emp_seq.NEXTVAL, 'John Doe');  
  
```
```

Sequences are used for generating primary key values.
